Isotropic Entanglement (Density of States of Quantum Spin Systems)

Ramis Movassagh¹ and Alan Edelman²

¹Department of Mathematics, Northeastern University ²Department of Mathematics, M.I.T.

Fields Institute, July 2013

F 4 3 F 4

The eigenvalue distribution: Motivation

Synonymous: (Energy) Spectrum; eigenvalue distribution, density of states, level densities etc.

- First step for all eigenvalue problems (e.g. quantum mechanics) of sums of matrices
- Physical: Partition function and therefore the thermodynamics of QMBS

The eigenvalue distribution: Motivation

Synonymous: (Energy) Spectrum; eigenvalue distribution, density of states, level densities etc.

- First step for all eigenvalue problems (e.g. quantum mechanics) of sums of matrices
- Physical: Partition function and therefore the thermodynamics of QMBS

<u>Goal</u>: Given the geometry, local spin states, and type of local interaction, capture the spectrum of the H.

Complexity issues

Note: Generally the Spectrum of QMBS is hard to find *"exactly"* (QMA-complete):

- F.G.S.L. Brandao's Thesis (2008).
- B. Brown, S. T. Flammia, N. Schuch (2010), "Computational Difficulty of Computing the Density of States".

Phys. Rev. Lett. 107, 040501 (2011)

The Slider Theorem

Theorem

(The Slider Theorem) The quantum kurtosis lies in between the classical and the iso kurtoses, $\gamma_2^{iso} \leq \gamma_2^q \leq \gamma_2^c$. Therefore there exists a $0 \leq p \leq 1$ such that $\gamma_2^q = p\gamma_2^c + (1-p)\gamma_2^{iso}$. Further, $\lim_{N\to\infty} p = 1$.

・ロト ・同ト ・ヨト ・ヨト

Universality of p

Corollary

(Universality) $p \mapsto p(N, d, \beta)$, namely, it is independent of the distribution of the local terms.

Here $\beta = 1$. Therefore, *p* only depends on eigenvectors!

Local terms: Wishart matrices

Suppose you have the first four moments

Ramis Movassagh arXiv: 1012.5039; Phys. Rev. Lett. 107, 097205 (2011)

Suppose you have the first four moments

Theoretical studies of localization, anomalous diffusion and ergodicity breaking require solving the electronic structure of disordered systems. We use free probability to approximate the ensembleaveraged density of states without exact diagonalization. We present an error analysis that quantifies the accuracy using a generalized moment expansion, allowing us to distinguish between different approximations. We identify an approximation that is accurate to the eighth moment across all noise strengths, and contrast this with the perturbation theory and isotropic entanglement theory.

Question for you: Why do we do so well?

$$m_{5} = \frac{1}{m} \mathbb{E} \operatorname{Tr} \left(A^{5} + 5A^{4} Q_{\bullet}^{T} B Q_{\bullet} + 5A^{3} Q_{\bullet}^{T} B^{2} Q_{\bullet} + 5A^{2} Q_{\bullet}^{T} B^{3} Q_{\bullet} + \frac{5A(AQ_{\bullet}^{T} BQ_{\bullet})^{2}}{5(AQ_{\bullet}^{T} BQ_{\bullet})^{2} Q_{\bullet}^{T} BQ_{\bullet} + 5AQ_{\bullet}^{T} B^{4} Q_{\bullet} + B^{5}} \right)$$

Question for you: Why do we do so well?

$$\begin{split} \mathbb{E} \mathrm{Tr} \left\{ \dots Q^{-1} B^{\geq 1} Q A^{\geq 1} Q^{-1} B^{\geq 1} Q \dots \right\} &\leq \\ \mathbb{E} \mathrm{Tr} \left\{ \dots Q_q^{-1} B^{\geq 1} Q_q A^{\geq 1} Q_q^{-1} B^{\geq 1} Q_q \dots \right\} &\leq \\ \mathbb{E} \mathrm{Tr} \left\{ \dots B^{\geq 1} A^{\geq 1} B^{\geq 1} \dots \right\} &. \end{split}$$

e.g.
$$\mathbb{E}\mathrm{Tr}\left\{\left(AQ^{-1}BQ\right)^{k}\right\} \leq \mathbb{E}\mathrm{Tr}\left\{\left(AQ_{q}^{-1}BQ_{q}\right)^{k}\right\} \leq \mathbb{E}\mathrm{Tr}\left\{\left(AB\right)^{k}\right\}$$

 $K > 2$
