| | | | | |

The experiment

Figure: Experimental results: the samples are placed in two separate test tubes of diameter 5mm and 8mm, and the smaller test tube is placed inside the larger. The inner test tube is filled with deoxygenated blood; the outer tube is filled with oxygenated blood. The two samples at equilibrium are shown on the left, where both appear as white; and the result after the optimal control is applied is shown on the right, where the inner sample appears black, corresponding to the saturation of the first spin, and magnitude of the other sample represents the remaining magnetization.

The Bloch equation and the saturation problem

Normalized magnetization vector of a spin 1/2 particle M = (x, y, z)System

$$\frac{dx}{dt} = -\Gamma x + u_2 z$$
$$\frac{dy}{dt} = -\Gamma y - u_1 z$$
$$\frac{dz}{dt} = \gamma (1 - z) + u_1 y - u_2 x$$

- $\gamma,\,\Gamma:$ parameters associated to the particle, and $2\Gamma\geq\gamma$
- N = (0, 0, 1): equilibrium point
- Control is a RF magnetic field, $u = (u_1, u_2)$, $|u| \le 2\pi$

- $M \in B(0,1)$, the Bloch ball
- |M|: "color" between 0 and 1

Set M from the north pole to zero in minimum time

Computation of the optimal solution

- Parameter $2\Gamma \ge 3\gamma$
- By symmetry of revolution one can restrict to 2D system $\dot{q} = F + uG$, $|u| \le 2\pi$

$$\begin{cases} \dot{y} = -\Gamma y - uz \\ \dot{z} = \gamma(1-z) + uy \end{cases}$$

• Simple system but complicated problem

| Pontrvagin | Maximum | Principle | | |
|------------|------------|------------------|---------------|------------------------|
| Experiment | Saturation | Contrast problem | Open problems | Singular flow analysis |
| 00 | ○●○○ | 0000000000 | | 0000000 |

Lift $(q, u) \rightarrow (q, p, u)$

Use the Pontryagin Maximum Principle (1956)

$$H = \langle p, \dot{q} \rangle = \langle p, F + uG \rangle$$

Necessary optimality condition for q^*, u^*

$$\begin{cases} \dot{q}^* = \frac{\partial H}{\partial p}(q^*, p^*, u^*) \\ \dot{p}^* = -\frac{\partial H}{\partial q}(q^*, p^*, u^*) \\ H(q^*(t), p^*(t), u^*(t)) = \max_{|v| \le 2\pi} H(q^*(t), p^*(t), v) \end{cases}$$

|------------|------------|------------------|---------------|------------------------|
| 00 | 0000 | | 00000000 | 0000000 |
| Optimal | solution | | | |

Two types of arcs forming an optimal solution

- $u^*(t) = 2\pi \operatorname{sgn} \langle p^*(t), G^*(q^*(t)) \rangle$, "bang-bang" arcs
- $\langle p^*(t), G^*(q^*(t))
 angle = 0$, "singular" arcs

Computation: two singular arcs, one horizontal and one vertical derive $\langle p^*(t), G^*(q^*(t)) \rangle = 0$:

$$\langle p, [G, F] \rangle = 0$$

 $\langle p, [[G, F], F] \rangle + u \langle p, [[G, F], G] \rangle = 0$

| 00 | 0000 | | 00000000 | 0000000 |

The maximum principle allows the computation of an optimal candidate using a SHOOTING METHOD

Shooting method

- Compute $p^*(0)$ at the initial time such that (q^*, p^*) is a solution of the maximum principle
- Problem is nonlinear and $p^*(0)$ is not unique
- An initial guess about p*(0) has to be known to compute the solution using a Newton method. To have such a guess and to determine a priori the structure BSBSBS of the solution we use the Hampath code (O. Cots, 2012).

Regularize Mayer problem into Bolza problem:

$$\min_{u(\cdot)} c(q^*(\mathcal{T})) + (1-\lambda) \int_0^{\mathcal{T}} |u(t)|^{2-\lambda} dt, \quad \lambda \in [0,1]$$

λ : homotopy parameter

Problem "smoothens" \rightarrow Newton method to determine the structure of the solution. Once the structure BSBS is known, compute the solution accurately using a multiple shooting method.

The maximum principle is only a necessary optimality condition.

- More conditions have to be found based on the concept of conjugate points.
- Sufficient optimality condition relies on the technique of extremal fields and the Hamilton-Jacobi-Bellman equation.

Remark

In the contrast problem there are many local minima which leads to a very complicated problem.
